

# Straight-line Drawings of Outerplanar Graphs in $O(dn \log n)$ Area

Fabrizio Frati\*

## Abstract

We show an algorithm for constructing  $O(dn \log n)$  area outerplanar straight-line drawings of  $n$ -vertex outerplanar graphs with degree  $d$ . Also, we settle in the negative a conjecture [1] on the area requirement of outerplanar graphs by showing that snowflake graphs admit linear area drawings.

## 1 Introduction

Almost thirty years ago, Dolev and Trickey [4] showed that every  $n$ -vertex outerplanar graph whose degree is bounded by 4 admits a poly-line drawing in  $\Theta(n)$  area. The techniques presented in [4] can be modified in order to obtain poly-line drawings of outerplanar graphs with degree  $d$  in  $O(d^2n)$  area, as pointed out in [1]. More recently, the problem of obtaining minimum area drawings of outerplanar graphs has been tackled by Biedl, who in [1] provided an  $O(n \log n)$  area upper bound for poly-line drawings of general outerplanar graphs. Moreover, she conjectured that there exists a class of outerplanar graphs called “snowflake graphs” requiring  $\Omega(n \log n)$  area in any planar straight-line or poly-line drawing. Concerning straight-line drawings, in [5] Garg and Rusu have shown that every  $n$ -vertex outerplanar graph has a straight-line drawing with  $O(dn^{1.48})$  area. However, a sub-quadratic area bound has been proved two years ago in [3], where Di Battista and Frati showed that for straight-line drawings of general outerplanar graphs  $O(n^{1.48})$  area always suffices.

In Section 3 we provide an algorithm for obtaining straight-line drawings of outerplanar graphs in  $O(dn \log n)$  area. Further, in Section 4 we show that snowflake graphs admit linear area drawings, settling in the negative the above cited conjecture appeared in [1]. In the same section we give conclusions and a conjecture concerning the area requirement of straight-line drawings of outerplanar graphs.

## 2 Preliminaries

We assume familiarity with Graph Drawing (see also [2]).

A *planar straight-line grid drawing* of a graph is such that each vertex is mapped to a point with integer coordinates, each edge is represented by a segment between its endpoints and no two edges cross, but, possibly, at common endpoints.

In the following, unless otherwise specified, for *drawing* we always mean planar straight-line grid drawing. Clearly, a straight-line drawing of a graph  $G$  is fully determined by the placement of the vertices of  $G$ . The *area* of a drawing is the number of grid points of the smallest rectangle with sides parallel to the axes that covers the drawing completely.

An *embedding* of a graph  $G$  is an ordering of the edges incident to each vertex. An embedding of  $G$  determines its *dual graph* that is the graph with one vertex per face of  $G$  and with one edge between two vertices if the corresponding faces share an edge in  $G$ . An *outerplanar embedding* is a planar embedding of a graph in which all vertices are incident to the same face, say the *external face*. An *outerplanar graph* is a graph that admits an outerplanar embedding. The dual graph of an outerplanar embedded graph is a tree when not considering the vertex corresponding to the external face. A *maximal outerplanar graph* is a graph that admits an outerplanar embedding in which all faces, but for the external one, are triangles. The dual graph of a maximal outerplanar embedded graph is a binary tree. The *degree of a vertex* is the number of edges incident to the vertex. The *degree of a graph* is the maximum degree of one of its vertices.

Let  $T$  be a binary tree rooted at node  $r$ . Let  $T(v)$  denote the subtree of  $T$  rooted at node  $v$ . The *leftmost path*  $L(T)$  (the *rightmost path*  $R(T)$ ) of  $T$  is path  $v_0, v_1, \dots, v_k$  such that  $v_0 = r$ ,  $v_{i+1}$  is the left child (resp. the right child) of  $v_i$ ,  $\forall i$  such that  $0 \leq i \leq k-1$ , and  $v_k$  doesn't have a left child (resp. a right child). The *left-right (right-left) path* of a node  $v \in T$  is path  $v_0, v_1, \dots, v_k$  such that  $v_0 = v$ ,  $v_1$  is the left (resp. right) child of  $v_0$ , and  $v_1, v_2, \dots, v_k$  is the rightmost (resp. leftmost) path of  $T(v_1)$ . Consider any drawing  $\Gamma$  of  $T$ . The *left polygon of the neighbors*  $P_l(v)$  (the *right polygon of the neighbors*  $P_r(v)$ ) of a node  $v \in T$  is the polygon of the segments representing in  $\Gamma$  the edges of the left-right (resp. right-left) path plus a segment connecting  $v_k$  and  $v_0$ .

A planar straight-line drawing  $\Gamma$  of a binary tree  $T$  is *star-shaped* if (1) it's order-preserving, i.e. the order of the children is the same of one fixed in advance; (2) for each node  $v \in T$ ,  $P_l(v) = (v, v_1, \dots, v_k)$  and  $P_r(v) = (v, u_1, \dots, u_p)$  are simple polygons and each segment  $(v, v_i)$ , with  $2 \leq i \leq k-1$  (resp.  $(v, u_j)$ , with  $2 \leq j \leq p-1$ ), belongs to the interior of  $P_l(v)$  (resp.  $P_r(v)$ ), but for its endpoints; (3) for each pair of nodes  $v_a, v_b \in T$ , each of  $P_l(v_a)$  and  $P_r(v_a)$  doesn't intersect  $P_l(v_b)$  and  $P_r(v_b)$ , but, possibly, at common endpoints or at common edges; and (4) there exist points  $p_l$  and  $p_r$  from which it's possible to draw edges to each node of  $L(T)$  and to each node of  $R(T)$ , respectively, and to draw edge  $(p_l, p_r)$ , without creating crossings with the edges of  $\Gamma$ .

\*Dipartimento di Informatica e Automazione, Università Roma Tre, frati@dia.uniroma3.it Work partially supported by MUR under Project MAINSTREAM – Algorithms for Massive Information Structures and Data Streams.

Let  $\mathcal{E}$  be an outerplanar embedding of a maximal outerplanar graph  $G$  and let  $T$  be the dual binary tree of  $\mathcal{E}$ . Select any edge  $(u_l, u_r)$  on the external face of  $\mathcal{E}$  and root  $T$  at the internal face containing  $(u_l, u_r)$ . We call vertices  $u_l$  and  $u_r$  *poles* of  $G$  and we also call *internal subgraph* the graph obtained by deleting  $u_l, u_r$ , and their incident edges from  $G$ .

In [3] the straight-line drawability of an  $n$ -vertex outerplanar graph  $G$  was strictly related to the “star-shaped” drawability of its dual tree  $T$ , by means of the following lemma:

**Lemma 1** [3] *If  $T$  admits a star-shaped drawing with  $f(n)$  area, then  $G$  has an outerplanar straight-line drawing where the area of the drawing of its internal subgraph is  $f(n)$ .*

The proof of the previous lemma is based on a bijection that can be established between the nodes of  $T$  and the vertices of  $G$ , but for its poles. Such a bijection allows to draw  $G$  by augmenting the star-shaped drawing of  $T$  with two extra points (representing the poles of  $G$ ) and with some extra straight-line edges. Hence, in a star-shaped drawing of  $T$  with area  $f(n)$ , it is sufficient to guarantee a placement for the poles of  $G$  not asymptotically increasing  $f(n)$  to be able to construct a drawing of  $G$  in  $O(f(n))$  area.

### 3 The algorithm

The outline of the algorithm is as follows: (i) augment the input outerplanar graph  $G$  to maximal; (ii) select any edge  $(u_l, u_r)$  on the external face of the outerplanar embedding  $\mathcal{E}$  of  $G'$  and root the dual binary tree  $T$  of  $\mathcal{E}$  at the internal face  $r$  of  $\mathcal{E}$  containing  $(u_l, u_r)$ ; construct a star-shaped drawing  $\Gamma$  of  $T$ ; (iii) insert the poles of  $G'$  and the edges that are needed to augment  $\Gamma$  in a drawing  $\Gamma'$  of  $G'$ ; (iv) remove the dummy edges inserted at the first step to obtain a drawing of  $G$ .

Step (i) can be performed by means of the algorithm described in [6], where it is shown that an outerplanar graph can be augmented to maximal by inserting dummy edges that don't asymptotically alter the degree of the graph.

Now we describe how to construct a star-shaped drawing  $\Gamma$  of  $T$ . The outline of such a construction is as follows. A path  $S$  is removed from  $T$ , together with the edges incident to the vertices of  $S$ . The subtrees that are disconnected from the removal of  $S$  are recursively drawn. Path  $S$  is chosen so that each one of such subtrees is “small”, that is, has at most  $n/2$  nodes. The drawings of the recursively drawn subtrees are horizontally aligned, namely they are all contained in an horizontal strip  $H$ . The vertical extension of such a strip is given by the height of the highest drawing of a subtree recursively drawn. The nodes of  $S$  are drawn in the *upper part* and in the *lower part* of the drawing, that is in the  $4d+1$  horizontal grid lines above and below  $H$ , respectively. In particular,  $S$  is partitioned in subpaths, and each subpath “cuts”  $H$ , that is, is drawn in part above and in part below  $H$ . The drawing satisfies the visibility properties of a star-shaped drawing. In particular, the leftmost and the rightmost path of  $T$  are placed on the lowest line intersecting the drawing.

Denote by  $h_1$  and  $h_2$  the horizontal grid lines delimiting  $H$  with  $h_1$  above  $h_2$  at a vertical distance that will be determined later. The  $4d+1$  horizontal grid lines above  $h_1$  (resp. below  $h_2$ ), that compose the upper part (resp. the lower part) of the drawing, are labeled  $u_1, u_2, \dots, u_{4d+1}$  (resp.  $l_1, l_2, \dots, l_{4d+1}$ ) from the lowest to the highest (resp. from the highest to the lowest). All nodes of  $L(T)$  and of  $R(T)$  lie on  $l_{4d+1}$ .

Assume  $T$  is rooted at any node  $r$  of degree at most 2. Select a path  $S = (v_0, v_1, \dots, v_m)$  in  $T$ , called *spine*, such that (a)  $v_0 = r$ , (b) for  $1 \leq i \leq k$ ,  $v_i$  is root of the subtree with the greatest number of nodes among the subtrees rooted at children of  $v_{i-1}$ , and (c)  $v_m$  is a leaf. The nodes of  $T$  belonging (not belonging) to  $S$  are *spine nodes* (*non-spine nodes*). We call *left edge* (*right edge*) an edge  $(v_{i-1}, v_i)$  of  $S$  such that  $v_i$  is the left (right) child of  $v_{i-1}$  in  $S$ .

Iteratively subdivide  $S$  in paths  $S_0, S_1, \dots, S_q$ , so that  $S_j = (v_{j,k}, v_{j,k+1}, \dots, v_{j,l}, v_{j,l+1}, \dots, v_{j,f-1}, v_{j,f})$ , for  $0 \leq j \leq q$ , is defined as follows:  $v_{0,k} = v_0$ , and, for  $1 \leq j \leq q$ ,  $v_{j,k}$  is the node after  $v_{j-1,f}$  in  $S$ . Suppose that  $(v_{j,k}, v_{j,k+1})$  is a right edge. Let  $v_{j,l}$  be the first node after  $v_{j,k}$  in  $S$  such that  $(v_{j,l}, v_{j,l+1})$  is a left edge. If  $(v_{j,l+1}, v_{j,l+2})$  is a left edge (right edge) then let  $v_{j,f}$  be the first node after  $v_{j,l}$  in  $S$  such that  $(v_{j,f}, v_{j,f+1})$  is a right (resp. left) edge. Now suppose that  $(v_{j,k}, v_{j,k+1})$  is a left edge. Let  $v_{j,l}$  be the first node after  $v_{j,k}$  in  $S$  such that  $(v_{j,l}, v_{j,l+1})$  is a right edge. If  $(v_{j,l+1}, v_{j,l+2})$  is a right edge (left edge) then let  $v_{j,f}$  be the first node after  $v_{j,l}$  in  $S$  such that  $(v_{j,f}, v_{j,f+1})$  is a left (resp. right) edge. Notice that  $S_q$  could have no vertex  $v_{q,l}$  or  $v_{q,f}$  if the spine ends before a left edge or a right edge is encountered.  $T$  is also subdivided in subtrees: For  $0 \leq j \leq q$ ,  $T_j$  is the subtree of  $T$  induced by the nodes in  $S_j$  and the nodes in the subtrees rooted at non-spine nodes children of spine nodes in  $S_j$ .

Now we show how to construct a drawing  $\Gamma_j$  of each  $T_j$ , for  $0 \leq j \leq q$ . We distinguish eight cases, based on whether (i)  $j$  is even (Cases 1-2-3-4) or odd (Cases 5-6-7-8); (ii)  $(v_{j,k}, v_{j,k+1})$  is a right edge (Cases 1-2-5-6) or a left edge (Cases 3-4-7-8); and (iii)  $(v_{j,l+1}, v_{j,l+2})$  is a right edge (Cases 1-3-5-7) or a left edge (Cases 2-4-6-8). In the cases in which  $j$  is even, draw  $L(T_j)$  and  $R(T_j)$  on  $l_{2d+1}$  so that the each node of  $L(T_j)$  (of  $R(T_j)$ ) is one unit to the right (to the left) of its left (right) child. In the cases in which  $j$  is odd, draw  $L(T_j)$  and  $R(T_j)$  on  $u_{2d+1}$  so that the each node of  $L(T_j)$  (of  $R(T_j)$ ) is one unit to the left (to the right) of its left (right) child. Denote by  $h_l$  the vertical grid line passing through  $v_l$ , and denote by  $h_{l+1}, h_{l+2}, h_{l-1}$ , and  $h_{l-2}$  the vertical grid lines one unit to the right, two units to the right, one unit to the left, and two units to the left of  $h_l$ , respectively.

**Case 1.** (see Fig. 1) Draw  $v_{j,f}$  at the intersection between  $h_{l+1}$  and  $u_{2d+2}$ ; draw  $R(T(v_{j,f}))$  on  $h_{l+1}$ , with any node one unit above its right child. Draw  $v_{j,f-1}$  at the intersection between  $h_{l-2}$  and  $u_{4d+1}$ . Draw  $R(T(v_{j,l+1}))$  till  $v_{j,f-1}$  on  $h_{l-2}$ , with any node one unit below its right child; draw  $L(T(v_{j,l+1}))$  on  $h_{l-2}$ , with any node one unit above its left

Figure 1: Thick segments represent the edges of  $S$ . Left (right) edges are labeled by  $l$  (resp. by  $r$ ).

child. **Case 2.** Draw  $v_{j,f}$  at the intersection between  $h_{l-2}$  and  $u_{4d+1}$ ; draw  $L(T(v_{j,f}))$  on  $h_{l-2}$ , with any node one unit above its left child. Draw  $v_{j,f-1}$  at the intersection between  $h_{l+1}$  and  $u_{2d+2}$ . Draw  $L(T(v_{j,l+1}))$  till  $v_{j,f-1}$  on  $h_{l+1}$ , with any node one unit below its left child; draw  $R(T(v_{j,l+1}))$  on  $h_{l+1}$ , with any node one unit above its right child. **Case 3.** Draw  $v_{j,f}$  at the intersection between  $h_{l+2}$  and  $u_{2d+2}$ ; draw  $R(T(v_{j,f}))$  on  $h_{l+2}$ , with any node one unit above its right child. Draw  $v_{j,f-1}$  at the intersection between  $h_{l-1}$  and  $u_{4d+1}$ . Draw  $R(T(v_{j,l+1}))$  till  $v_{j,f-1}$  on  $h_{l-1}$ , with any node one unit below its right child; draw  $L(T(v_{j,l+1}))$  on  $h_{l-1}$ , with any node one unit above its left child. **Case 4.** (see Fig. 1) Draw  $v_{j,f}$  at the intersection between  $h_{l-1}$  and  $u_{4d+1}$ ; draw  $L(T(v_{j,f}))$  on  $h_{l-1}$ , with any node one unit above its left child. Draw  $v_{j,f-1}$  at the intersection between  $h_{l+2}$  and  $u_{2d+2}$ . Draw  $L(T(v_{j,l+1}))$  till  $v_{j,f-1}$  on  $h_{l+2}$ , with any node one unit below its left child; draw  $R(T(v_{j,l+1}))$  on  $h_{l+2}$ , with any node one unit above its right child. **Case 5.** (see Fig. 1) Draw  $v_{j,f}$  at the intersection between  $h_{l-1}$  and  $l_{4d+1}$ ; draw  $R(T(v_{j,f}))$  on  $h_{l-1}$ , with any node one unit below its right child. Draw  $v_{j,f-1}$  at the intersection between  $h_{l+2}$  and  $l_{2d+2}$ . Draw  $R(T(v_{j,l+1}))$  on  $h_{l+2}$ , with any node one unit above its right child; draw  $L(T(v_{j,l+1}))$  on  $h_{l+2}$ , with any node one unit below its left child. **Case 6.** Draw  $v_{j,f}$  at the intersection between  $h_{l+2}$  and  $l_{2d+2}$ ; draw  $L(T(v_{j,f}))$  on  $h_{l+2}$ , with any node one unit below its left child. Draw  $v_{j,f-1}$  at the intersection between  $h_{l-1}$  and  $l_{4d+1}$ . Draw  $L(T(v_{j,l+1}))$  on  $h_{l-1}$ , with any node one unit above its left child; draw  $R(T(v_{j,l+1}))$  on  $h_{l-1}$ , with any node one unit below its right child. **Case 7.** Draw  $v_{j,f}$  at the intersection between  $h_{l-2}$  and  $l_{4d+1}$ ; draw  $R(T(v_{j,f}))$  on  $h_{l-2}$ , with any node one unit below its right child. Draw  $v_{j,f-1}$  at the intersection between  $h_{l+1}$  and  $u_{2d+2}$ . Draw  $R(T(v_{j,l+1}))$  on  $h_{l+1}$ , with any node one unit above its right child; draw  $L(T(v_{j,l+1}))$  on  $h_{l+1}$ , with any node one unit below its left child. **Case 8.** Draw  $v_{j,f}$  at the intersection between  $h_{l+1}$  and  $l_{2d+2}$ ; draw  $L(T(v_{j,f}))$  on  $h_{l+1}$ , with any node one unit below its left child. Draw  $v_{j,f-1}$  at the

intersection between  $h_{l-2}$  and  $l_{4d+1}$ . Draw  $L(T(v_{j,l+1}))$  on  $h_{l-2}$ , with any node one unit above its left child; draw  $R(T(v_{j,l+1}))$  on  $h_{l-2}$ , with any node one unit below its right child.

In  $\Gamma_0$  shift the nodes of  $L(T_0)$  and  $R(T_0)$  vertically, so that they keep the same  $x$ -coordinates and lie on line  $l_{4d+1}$ .

For each  $T_j$ , with  $0 \leq j \leq q$ , recursively construct a drawing of each subtree rooted at a node of  $T_j$  that has not been already drawn and that is child of a node of  $T_j$  that has been already drawn. Let  $h_{max}$  be the maximum between the heights of the drawings of the subtrees recursively drawn. Set the distance between  $h_1$  and  $h_2$  to be  $h_{max} - 1$ . For each  $T_j$ , with  $0 \leq j \leq q$  and  $j$  even, consider the drawings of the subtrees rooted at non-already drawn nodes of  $T_j$  that are children of nodes belonging to  $L(T_j)$  or to  $R(T_j)$ , and whose parents are placed to the right (to the left) of  $v_{j,l}$ . Place such drawings in the left-right order induced by the order of their parents on  $l_{4d+1}$  or on  $l_{2d+1}$ , at one unit of horizontal distance between them, with the leftmost (resp. rightmost) vertical line intersecting the leftmost (resp. rightmost) drawing one unit to the right (resp. to the left) of the last node of  $R(T_j)$  (resp. of  $L(T_j)$ ), and with their leftmost and rightmost paths on  $h_1$ . Then, consider the drawings of the subtrees rooted at non-already drawn nodes of  $T_j$  that are children of nodes already drawn. Rotate such drawings of  $\pi$  radians and place them so that  $L(T_j)$  and  $R(T_j)$  lie on  $h_2$ , so that the drawings of the subtrees rooted at children of nodes drawn on  $h_{l+1}$  or on  $h_{l+2}$  (on  $h_{l-1}$  or on  $h_{l-2}$ ) are placed to the right (resp. to the left) of the drawing constructed up to now, at one unit of horizontal distance in the order induced by their parents in  $L(T(v_{j,l+1}))$  or in  $R(T(v_{j,l+1}))$ . If  $j$  is odd, a drawing  $\Gamma_j$  of  $T_j$  can be constructed analogously.

Now place all the  $\Gamma_j$ 's together, starting from  $\Gamma_0$ , and iteratively adding  $\Gamma_j$ , for  $j = 1, \dots, m$ , so that the leftmost vertical line intersecting  $\Gamma_j$  is one unit to the right of the rightmost vertical line intersecting  $\Gamma_{j-1}$ .

The constructed drawing  $\Gamma$  of  $T$  is star-shaped (see the full version of the paper). Let's analyze the area requirement

of  $\Gamma$ . Since there is at least one node for each vertical grid line intersecting  $\Gamma$ , the width of  $\Gamma$  is  $O(n)$ . The height of  $\Gamma$  is the sum of the heights of  $H$ , of the upper part of  $\Gamma$ , and of the lower part of  $\Gamma$ . The height of  $H$  is equal to the height of the highest subtree of  $T$  recursively drawn; by definition of  $S$ , each subtree recursively drawn has at most  $n/2$  nodes. Denoting by  $H(n)$  the maximum height of a drawing of an  $n$ -nodes tree  $T$  constructed by the algorithm, we get:  $H(n) = (4d+1) + (4d+1) + H(n/2) = O(d) + H(n/2) = O(d \log n)$ .

Place the poles of  $G'$  both on the horizontal line one unit below  $v_0$ , so that they are at distance of one horizontal unit, and so that one pole is on the same vertical line of  $v_0$ . Notice that this placement doesn't asymptotically increase the area of  $\Gamma$ . Finally, the edges necessary to augment  $\Gamma$  in a drawing of  $G'$  can be inserted and the dummy edges inserted in the first step can be removed obtaining a drawing of  $G$ .

**Theorem 2** Any  $n$ -vertex outerplanar graph of degree  $d$  has a straight-line outerplanar drawing in  $O(dn \log n)$  area.

**Corollary 3** Any  $n$ -vertex outerplanar graph with constant degree has a straight-line outerplanar drawing in  $O(n \log n)$  area.

#### 4 Conclusions and Conjectures

In this paper we have shown that  $O(dn \log n)$  area is always achievable for straight-line drawings of outerplanar graphs.

In [1] Biedl conjectured an  $\Omega(n \log n)$  lower bound on the area requirement of straight-line and poly-line drawings of outerplanar graphs. More precisely, she exhibited a class of outerplanar graphs, the "snowflake graphs" shown in Fig. 2.a, for which she claimed:

Figure 2: (a) A snowflake graph. (b) A snowflake graph subdivided in three complete outerplanar graphs. (c) Drawing of snowflake graphs in linear area. The shaded regions correspond to the three copies of the drawing of the internal subgraph of a complete outerplanar graph constructed by the algorithm in [3].

**Conjecture A** [1] Any poly-line drawing of the snowflake graph has  $\Omega(n \log n)$  area.

It can be observed that an  $n$ -vertex snowflake graph is composed of three identical  $O(n)$ -vertex complete outer-

planar graphs (see Fig. 2.b), defined in [3] as the outerplanar graphs whose dual graphs are complete binary trees. For complete outerplanar graphs an  $O(\sqrt{n}) \times O(\sqrt{n})$  area straight-line drawing algorithm has been presented in [3]. Such an algorithm constructs drawings in which the vertices of the internal subgraph that are connected to the poles lie on two half-lines  $l_1$  and  $l_2$  with a common endpoint and with slopes  $-\pi/4$  and  $\pi/4$ . The entire drawing of the internal subgraph lies in the wedge with angle  $\pi/2$  delimited by  $l_1$  and  $l_2$ . Hence, considering three copies of the drawing of the internal subgraph of a complete outerplanar graph constructed by the algorithm in [3], rotating them of  $0$ ,  $\pi$ , and  $3\pi/2$ , respectively, placing the drawings together, and inserting the three vertices that are poles for the three complete outerplanar graphs, an  $O(\sqrt{n}) \times O(\sqrt{n})$  area straight-line drawing of a snowflake graph can be obtained (see Fig. 2.c).

We would like to point up that all known algorithms for constructing straight-line drawings of general outerplanar graphs try to minimize the extension of the drawing in only one coordinate dimension, while allowing the other dimension to be  $O(n)$ . However, we believe that  $O(n \log n)$  area cannot be achieved by squeezing the drawing in only one dimension, and that hence a compaction in both dimensions (or a proof that one dimension is  $\Omega(n)$ ) should be pursued.

**Conjecture 1** There exist  $n$ -vertex outerplanar graphs that in any straight-line drawing in which one dimension is  $O(n)$  require  $\omega(\log n)$  in the other dimension.

We notice that there exist outerplanar graphs such that both the width and the height of any grid drawing are  $\Omega(\log n)$  (e.g., outerplanar graphs containing a complete binary tree as a subgraph).
